

Syntax and Semantics: Exercise Session 13

Exercise 1.

Consider the following grammar for arithmetic expressions \mathbb{A} :

$$n ::= 0 \mid s(n) \qquad a ::= n \mid a + a \mid a * a$$

Intuitively, $s(n)$ is the successor of n , e.g., $s(0)$ and $s(s(0))$ encodes 1 and 2, respectively.

- 1) Let the set of states be \mathbb{A} , the set of final states be $\{0, s(0), s(s(0)), s(s(s(0))), \dots\}$ and consider the following *small step* transition rules for addition:

$$\begin{array}{ll} [r_1] & s(n_1) + n_2 \Rightarrow n_1 + s(n_2) \\ [r_2] & 0 + a \Rightarrow a \\ [r_3] & a_1 + a_2 \Rightarrow a_2 + a_1 \\ [r_4] & \frac{a_1 \Rightarrow a'_1}{a_1 + a_2 \Rightarrow a'_1 + a_2} \end{array}$$

Prove $s(s(s(0))) + s(s(0)) \Rightarrow^* s(s(s(s(s(0))))))$ using $[r_1], \dots, [r_4]$. All intermediate computations have to be proven. (Intuitively, this corresponds to deducing $3+2 = 5$.)

- 2) Complete the *small step* semantics from 1) by providing the rules for multiplication.

Note: The complete semantics of \mathbb{A} is intended to be the same as for arithmetic expressions in the language **Bims** from Hans Hüttel’s book but with the modified representation of numbers as explained above.

- 3) Using the transition rules from 1) and 2), prove $s(s(0)) * s(s(0)) \Rightarrow^* s(s(s(s(0))))$.
All intermediate computations have to be proven.

$$\begin{aligned} 1) \quad & s(s(s(0))) + s(s(0)) \stackrel{r_3}{=} s(s(0)) + s(s(s(s(0)))) \\ & \stackrel{r_1}{=} s(0) + s(s(s(s(s(0)))))) \\ & \stackrel{r_1}{=} 0 + s(s(s(s(s(s(0)))))) \\ & \stackrel{r_2}{=} s(s(s(s(s(s(s(0))))))) \end{aligned}$$

$$2) \quad [m_1] \quad s(n_1) * n_2 \Rightarrow n_1 * n_2 + n_2$$

$$[m_2] \quad s(0) * a \Rightarrow a$$

$$[m_3] \quad a_1 * a_2 \Rightarrow a_2 * a_1$$

$$[m_4] \quad \frac{a_1 \Rightarrow a_1'}{a_1 * a_2 \Rightarrow a_1' * a_2}$$

$$3) \quad s(s(0)) * s(s(0)) \xRightarrow{m_1} s(0) * s(s(0)) + s(s(0))$$

$$\left\{ m_4 \frac{s(0) * s(s(0)) \xRightarrow{m_2} s(s(0))}{s(0) * s(s(0)) + s(s(0)) \Rightarrow s(s(0)) + s(s(0))} \right\} \xrightarrow{\quad} \begin{array}{c} \Downarrow m_2 + m_4 \\ s(s(0)) + s(s(0)) \\ r_1 \Downarrow \\ s(0) + s(s(s(0))) \\ r_1 \Downarrow \\ 0 + s(s(s(s(0)))) \\ r_2 \Downarrow \\ s(s(s(s(0)))) \end{array}$$

Exercise 2.

Consider the arithmetic and boolean expressions from Chapter 4 in Hans Hüttel's book that have been extended by the existential (\exists) and the universal (\forall) quantifier:

$$a ::= n \mid x \mid a_1 + a_2 \mid a_1 * a_2 \mid a_1 - a_2 \mid (a_1)$$

$$b ::= a_1 = a_2 \mid a_1 < a_2 \mid \neg b_1 \mid b_1 \wedge b_2 \mid b_1 \rightarrow b_2 \mid (b_1) \mid \exists x.(b_1) \mid \forall x.(b_1)$$

1. Consider the following *big step* transition rules for the existential quantifier:

$$[\exists_1] \frac{s[x \mapsto v] \vdash b_1 \rightarrow_b \mathbf{tt}}{s \vdash \exists x.(b_1) \rightarrow_b \mathbf{tt}} \text{ FOR SOME } v \in \mathbb{Z}$$

$$[\exists_2] \frac{s[x \mapsto v] \vdash b_1 \rightarrow_b \mathbf{ff}}{s \vdash \exists x.(b_1) \rightarrow_b \mathbf{ff}} \text{ FOR ALL } v \in \mathbb{Z}$$

By combining the above rules with those from the book of Hans Hüttel, evaluate the expression $\exists x.(x * x = 4)$ in the state $s = [x \mapsto 0]$ to its truth value.

2. Provide the *big step* transition rules for the universal quantifier.

$$2) [\forall_1] \frac{s[x \mapsto v] \vdash b_1 \rightarrow_b \mathbf{tt}}{s \vdash \forall x.(b_1) \rightarrow_b \mathbf{tt}} \text{ for all } v \in \mathbb{Z}$$

$$[\forall_2] \frac{s[x \mapsto v] \vdash b_1 \rightarrow_b \mathbf{ff}}{s \vdash \forall x.(b_1) \rightarrow_b \mathbf{ff}} \text{ for some } v \in \mathbb{Z}$$

1)

$$\begin{array}{l} \text{Var}_{BSS} \quad \frac{}{} \\ \text{Mult}_{BSS} \quad \frac{s[x \mapsto 2] \vdash x \rightarrow_a 2}{s[x \mapsto 2] \vdash x * x \rightarrow_a 4} \quad \text{Num}_{BSS} \quad \frac{}{s[x \mapsto 2] \vdash \underline{4} \rightarrow_a 4} \\ \text{Eq}_{BSS} \quad \frac{}{s[x \mapsto 0] [x \mapsto 2] \vdash x * x = \underline{4} \rightarrow_b \mathbf{tt}} \\ \exists_1 \quad \frac{s[x \mapsto 0] [x \mapsto 2] \vdash x * x = \underline{4} \rightarrow_b \mathbf{tt}}{s[x \mapsto 0] \vdash \exists x.(x * x = \underline{4}) \rightarrow \mathbf{tt}} \end{array}$$

(Note: $s[x \mapsto 0] [x \mapsto 2] = s[x \mapsto 2]$)

3

Exercise 4.

Consider the language $L'' = \{w \in \Sigma^* \mid w = a^n \text{ with } n \geq 1\}$ over the singleton alphabet $\Sigma = \{a\}$. With this, consider the big step transitions $\rightarrow \subseteq L'' \times \mathbb{N}$ given by

$$[r_1] \frac{}{a \rightarrow 1} \qquad [r_2] \frac{w \rightarrow k}{aw \rightarrow k'} \quad k' = k \cdot |aw|,$$

where $|aw|$ denotes the length of the word aw .

1. Using the big step semantics, prove $aa \rightarrow 2$ and $aaa \rightarrow 6$.
2. Using the big step semantics and induction, prove that $a^n \rightarrow v$ with $v = 1 \cdot 2 \cdot \dots \cdot n$ for all $n \geq 1$. Note that a^n is the word consisting of n symbols a .

$$1) \quad \begin{array}{l} r_1 \frac{}{a \rightarrow 1} \\ r_2 \frac{}{aa \rightarrow 2} \quad 2 = 1 \cdot |aa| \\ r_2 \frac{}{aaa \rightarrow 6} \quad 6 = 2 \cdot |aaa| \end{array}$$

$$2) \quad \underline{n=1}: \quad a^1 \rightarrow 1 \quad \text{because } r_1 \frac{}{a \rightarrow 1}$$

$$\underline{n \rightarrow n+1}: \quad \text{By I.H., we have } a^n \rightarrow n!.$$

With this, we obtain

$$r_1 \frac{a^n \rightarrow n!}{aa^n \rightarrow k'} \quad k' = n! \cdot |aa^n| = n! \cdot (n+1) = (n+1)!,$$

thus implying $a^{n+1} \rightarrow (n+1)!$

Exercise 4.

Consider the language $L'' = \{\underline{0}, \underline{1}\}^+$ of binary strings. With this, we consider the big step semantics $\rightarrow \subseteq L'' \times \mathbb{N}$ given by

$$[r_0] \frac{}{\underline{0} \rightarrow 0}, \quad [r_1] \frac{}{\underline{1} \rightarrow 1}, \quad [r_2] \frac{w \rightarrow k'}{\underline{0}w \rightarrow k} k = k', \quad [r_3] \frac{w \rightarrow k'}{\underline{1}w \rightarrow k} k = 2^{|w|} + k'$$

As usual, $|w|$ denotes the length of w , while σw stands for a concatenation of $\sigma \in \{\underline{0}, \underline{1}\}$ and $w \in L''$. Essentially, \rightarrow assigns each binary string its decimal value (i.e., the value represented by the string with 2 as the base of the numeral system).

1) Using the big step semantics, prove $\underline{10} \rightarrow 2$ and $\underline{110} \rightarrow 6$.

2) Consider the language of ternary strings $L''' = \{\underline{0}, \underline{1}, \underline{2}\}^+$. Provide the big step semantics $\rightarrow_3 \subseteq L''' \times \mathbb{N}$ that maps each ternary string to its decimal value (i.e., the value represented by the string with 3 as the base of the numeral system).

[Hint: You may wish to double check your semantics by showing $\underline{12} \rightarrow_3 5$ and $\underline{212} \rightarrow_3 23$. This is only a suggestion and does not contribute to the score.]

1)

$$r_3 \frac{r_0 \frac{}{\underline{0} \rightarrow 0}}{\underline{10} \rightarrow 2} \quad 2 = 2^{|\underline{0}|} + 0 \quad \left\{ \begin{array}{l} \dots \\ \underline{10} \rightarrow 2 \\ \dots \end{array} \right. \quad r_3 \frac{\left\{ \dots \right\}}{\underline{110} \rightarrow 6} \quad 6 = 2^{|\underline{10}|} + 2$$

2)

$$t_0 \frac{}{\underline{0} \rightarrow 0} \quad t_1 \frac{}{\underline{1} \rightarrow 1} \quad t_2 \frac{}{\underline{2} \rightarrow 2}$$

$$t_3 \frac{w \rightarrow h'}{\underline{0}w \rightarrow h} h = h' \quad t_4 \frac{w \rightarrow h'}{\underline{1}w \rightarrow h} h = 3^{|w|} + h'$$

$$t_5 \frac{w \rightarrow h'}{\underline{2}w \rightarrow h} h = 2 \cdot 3^{|w|} + h'$$
